

INFORMATION TO USERS

This manuscript has been reproduced from the microfilm master. UMI films the text directly from the original or copy submitted. Thus, some thesis and dissertation copies are in typewriter face, while others may be from any type of computer printer.

The quality of this reproduction is dependent upon the quality of the copy submitted. Broken or indistinct print, colored or poor quality illustrations and photographs, print bleedthrough, substandard margins, and improper alignment can adversely affect reproduction.

In the unlikely event that the author did not send UMI a complete manuscript and there are missing pages, these will be noted. Also, if unauthorized copyright material had to be removed, a note will indicate the deletion.

Oversize materials (e.g., maps, drawings, charts) are reproduced by sectioning the original, beginning at the upper left-hand corner and continuing from left to right in equal sections with small overlaps. Each original is also photographed in one exposure and is included in reduced form at the back of the book.

Photographs included in the original manuscript have been reproduced xerographically in this copy. Higher quality 6" x 9" black and white photographic prints are available for any photographs or illustrations appearing in this copy for an additional charge. Contact UMI directly to order.

STRUCTURAL AND THERMAL EFFICIENCY OF PRECAST CONCRETE SANDWICH PANEL SYSTEMS

Amin Einea, Ph.D.

University of Nebraska, 1992

Advisers: Maher K. Tadros and David C. Salmon

Precast concrete sandwich panels (PCSP) are structurally and thermally efficient elements used for exterior walls in multi-unit residential, commercial, and warehouse buildings throughout the world. A typical PCSP consists of two precast reinforced concrete layers (called wythes) separated by a layer of insulation and connected with connectors which penetrate the insulation layer. The connectors used in the majority of available PCSP systems consist of concrete webs or blocks, steel elements, or a combination thereof. Because of their low thermal resistance, steel and concrete connectors can cause significant reduction in the effective thermal resistance of the panel through thermal bridging. The objective of this research is to develop a connecting system capable of improving the thermal and structural performance of PCSPs.

This dissertation first presents a review of existing PCSP systems. Next, evaluation of selected fiber reinforced plastic (FRP) connectors is summarized. The structural performance of a few FRP connectors is evaluated through a series of pure-shear (push-out) tests performed on small scale specimens. The initial evaluation and the first phase of testing led to the selection of a FRP bent-bar connector. The bar is fabricated in a

a deformed spiral shape through which a pair of prestressing strands or reinforcing bars can be threaded to provide anchorage in the concrete wythes. Phase two (pure shear tests) and phase three (flexural tests) were performed on small scale specimens to evaluate the structural performance of the bent-bar connector. In addition, the structural performance of the connector was analytically evaluated by developing finite element models for panel behavior in testing phases two and three. Experimental and analytical results from finite element and differential equation analysis are in good correlation.

This dissertation also includes a brief study of stresses and deformation due to differential volume changes. Volume changes often contribute a large portion of the stress or out-of-plane deflection of PCSPs. The finite element model, calibrated with the results of testing phase three, is used to evaluate the effectiveness of the differential equations for computing deflections due to differential volume changes. Both methods are compared with a practical design method for evaluating stresses and out-of-plane deflection due to differential volume changes.

ACKNOWLEDGEMENT

This dissertation was prepared as a part of a research project on "Energy Optimization of Precast Concrete Sandwich Panels," sponsored by the Nebraska Energy Office, Wilson Concrete Company, and the Center for Infrastructure Research at the University of Nebraska-Lincoln. This entire project was planned, guided, and supervised by Dr. Maher K. Tadros, Cheryl W. Prewett Professor of Civil Engineering, Director of Center for Infrastructure Research; and by Dr. David C. Salmon, Assistant Professor, University of Nebraska. Their advise and assistance in completing this dissertation are greatly appreciated.

My sincere appreciation is due to everyone who contributed to the success of this project including the following individuals: Jagdish Nijhawan, Morrie Workman, and Ken Rech of Wilson Concrete Company; Gyula J. Fogarasi, former visiting professor, Dr. Joseph V. Benak, Chairman of Civil Engineering and professor, Todd D. Culp, graduate assistant, University of Nebraska; and Phillip Catsman, Vega Technologies, Inc.

I wish to express my special regards to Leo A. Daly Company for their support and for allowing me to finish this dissertation while working for them.

Last but not least, my great appreciation to my wife Elham for her support, patience, and understanding.

To my parents

TERMINOLOGY

Some of the terminology used in this paper is defined below and in Chapter I.

Connectors: Various concrete, steel, or plastic elements that penetrate the insulation layer and connect the concrete wythes in PCSPs.

Fully Composite Panels: Sandwich panels whose wythes are connected in such a way that both wythes resist the applied flexural loads as if they were an integrated section.

Non-Composite Panels: Sandwich panels in which the two concrete wythes are connected with elements (connectors) that have no capacity for longitudinal shear transfer.

Open/Closed-Cell Insulation: Cellular insulation in which gas can/cannot readily pass from one cell to another. In closed-cell insulation, cells are primarily independent of one another preventing the movement of gas between the cells and thereby reducing the temperature transmission between neighboring cells.

Partially Composite Panels: Sandwich panels in which the connectors ^{xi} can transfer between zero and 100% of the longitudinal shear required for fully composite panel.

R-value ($^{\circ}\text{F}\cdot\text{ft}^2\cdot\text{h}/\text{Btu}$): is the thermal resistance, equals to the reciprocal of the thermal conductance which is defined as the number of British thermal units (Btu) which passes through a one square foot area of material in one hour if the temperature difference between both surfaces of the material is one degree Fahrenheit.

U-value ($\text{Btu}/^{\circ}\text{F}\cdot\text{ft}^2\cdot\text{h}$): is the reciprocal of thermal resistance ($U=1/R$).

PREVIEW

Chapter I

INTRODUCTION

Precast concrete sandwich panels (PCSP) are composed of two reinforced concrete layers (called wythes) separated by a layer of insulation. The concrete wythes are connected through the insulation layer by concrete webs, metal connectors, plastic connectors, or a combination of these elements, Figure 1.1.

PCSPs are favored as wall panels over other construction materials because of their superior thermal and structural efficiency. PCSP walls require "lower peak loads by about 13% for heating and 30% for cooling" than insulated metal or wood-framed walls having the same U-value under the same heat gradient conditions [1]. However, these values ignore the significant thermal efficiency loss due to using thermally conducting connectors such as steel and concrete connectors.

The main objective of the research project summarized in this dissertation is to devise a PCSP system to maximize its thermal efficiency while maintaining its structural efficiency. This system is designed for use in low rise commercial buildings and warehouses. It consists of PCSPs spanning 12 ft to 55 ft vertically and ranging in width from 4 ft to 12 ft, and are produced in long fixed or rolling (moving) beds.

PCSPs can be non-composite, partially composite, or fully composite panels depending on the percent of composite action they possess. A technical definition of the percent composite action in PCSPs is not well established in the literature. The general structural definition of composite action, however, can be summarized as follows. The definition of composite action differs between that defined under service loads and that

Figure 1.1. Typical load-bearing PCSP wall.
